Numerical solutions for G² Hermite interpolation problem with spirals

A. K.

October 31, 2019

This project is intended to provide a numerical solution (or several solutions) of the two-point G^2 Hermite interpolation problem with spirals.

I. e., a transition curve, joining two given points A and B, is constructed, matching given tangents and curvatures at A and B (Figure 1). Spirality means the monotonicity of the Chesaro equation of the transition curve: function

$$k(s) \equiv \tau'_s(s)$$

is monotonous (k being curvature, s arc length, and τ the direction of the tangent to the curve).

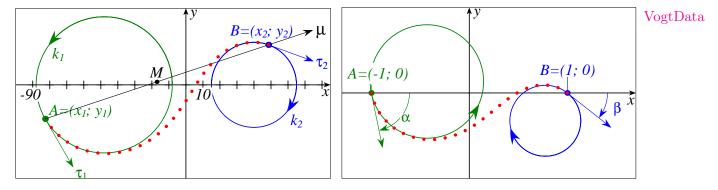

Figure 1. Example of 2-point G^2 Hermite data (boundary conditions).

The left picture in Figure 1 shows the example of 2-point G^2 Hermite data as: point $A = (x_1, y_1)$, tangent τ_1 and curvature k_1 at A, point $B = (x_2, y_2)$, tangent τ_2 and curvature k_2 at B. Namely,

$$x_1 = -82.64,$$
 $y_1 = -20.,$ $\tau_1 = 300.0^{\circ},$ $k_1 = 0.025;$ $x_2 = 48.55,$ $y_2 = 23.5,$ $\tau_2 = -20.0^{\circ},$ $k_2 - 0.04;$

Dotted curve is a an example of a spiral, matching this data. Its curvature is decreasing $(k_1 > k_2)$, and has an inflection (due to $k_1 k_2 < 0$).

Normalization of given G^2 **data.** The right picture in Figure 1 shows the same data brought to *normalized position*, i. e. to the local coordinate system, aligned with the chord. Denote 2c the chord length, and μ its direction:

$$c = \frac{1}{2} \left| AB \right|, \quad \mu = \arg \left[x_2 - x_1 + \mathrm{i} (y_2 - y_1) \right] = \mathtt{atan2} (y_2 - y_1, \; x_2 - x_1).$$

Normalization involves:

- moving point M = (A+B)/2 to the coordinate origin;
- rotating by the angle $-\mu$ to align the chord \overrightarrow{AB} with the x-axis;
- scaling (homothety) by the factor c^{-1} such that $A \to (-1; 0), B \to (1; 0)$.

In this coordinate system the boundary conditions are transformed to:

$$(x_1, y_1) \to (-1; 0), \quad \tau_1 \to \alpha = \tau_1 - \mu, \quad k_1 \to a = k_1 c;$$

 $(x_2, y_2) \to (+1; 0), \quad \tau_2 \to \beta = \tau_2 - \mu, \quad k_2 \to b = k_2 c.$

The program shows given data and solutions in both original (Page 1) and normalized coordinate systems (Page 2 and pages for every solution found). Additional transformation is used in calculations, transforming the case of decreasing curvature into increasing one by the the symmetry about the x-axis.

Existence of solutions. The above transformations do no affect the values of the invariants Q (1) and $\sigma = \alpha + \beta$ (invariance of σ may require corrections $\alpha \to \alpha \pm 2\pi$, $\beta \to \beta \pm 2\pi$).

• A spiral arc (non-biarc), matching given 2-point G^2 data exists iff

$$Q = (k_1 c + \sin \alpha)(k_2 c - \sin \beta) + \sin^2 \frac{\alpha + \beta}{2} < 0.$$
 (1)

• A *short* spiral is a spiral arc which does not turn near endpoints. A *short* spiral arc exists if, additionally,

if
$$k_1 < k_2$$
: $-\pi < \alpha, \beta \le \pi$, $\alpha + \beta > 0$;
if $k_1 > k_2$: $-\pi \le \alpha, \beta < \pi$, $\alpha + \beta < 0$

Short-
(2)_{ness}

 $[\operatorname{sgn}(\alpha+\beta) = \operatorname{sgn}(k_2 - k_1) \neq 0].$

 \bullet This method finds solution (s) if

$$0 < |\sigma| \leqslant \pi.$$
 (3) SigmaPi

This includes all convex spirals $(k_1k_2 \ge 0)$ and some spirals with inflection (e.g., one-to-one projectable on the chord).

• A long spiral arc will be constructed if...

In the below description some family parameter Φ (Phi), $0 \le |\Phi| \le \Phi_{max} \le 90^{\circ}$, is introduced to parametrize the family of solutions. The above conditions being satisfied, at least one solution [1], that for $\Phi = 0$, always exists. It is the unique solution in the critical case $|\sigma| = \pi$.

Brief description of the method ... see [1, 2] for details.

¹Another method will be possibly added to this script (or the special script will be added) which solves the problem for any α, β, k_1, k_2 and multiple winding, provided that the necessary condition (1) holds.

1. Running the program

The program is written in PostScrpit language. You need some PostScript (GhostScript) interpreter to be inslalled. Under Linux it is usually gv or gs. Under Windows it is gsview or console application gswin32c.

You may edit a few lines in the file G2spiral.ps to include your own boundary conditions (user data), and to run the program as gv G2spiral.ps

(or from file explorer). Example of user input to construct the spiral in Figure 1:

```
/UserG2Data [/XYTK8 -82.64 -20. 300 0.025 48.55 23.5 -20.0 -0.04 ]
```

Alternatively, you can store user data in a separate file, say, mydata1.ps, and run the program as

```
gs -dNOSAFER -sFname=/home/ak/G2spiral/mydata1.ps G2spiral.ps
or (comments to NOSAFER option...)
cat gv     -arg="-sFname=/home/ak/G2spiral/mydata1.ps" G2spiral.ps
or
cat mydata1.ps G2spiral.ps > tmp.ps
gv    tmp.ps
Conversion to pdf by ImageMagick convert utility (requires GhostScript to be preinstalled):
convert G2spiral.ps G2spiral.pdf
or by
ps2pdf tmp.ps mydata1.pdf
(see doc/Example-Converted_to_pdf.pdf).
```

2. Setting user data

A few comments on PS syntax. Only data types, used in setting user data, are briefly commented below.

Example of a file with user data. User data is stored as a dictionary named WorkData like

Only the first key-value pair, /UserG2Data [array], is obligatory. Its possible versions are described below. The 1-st element of the array is some /method, followed by 2–8 numeric arguments.

- 1. [/XYTK8 x1 y1 tau1 k1 x2 y2 tau2 k2] Direct setting of boundary conditions. 8 arguments are $x_1, y_1, \tau_1, k_1, x_2, y_2, \tau_2, k_2$.
- 2. [/Norm4 alpha k1 beta k2]
 Data normalized to the unit chord:

$$(x_1, y_1) = (-1, 0), \quad \tau_1 = \alpha, \quad k_1, \qquad (x_2, y_2) = (1, 0), \quad \tau_2 = \beta, \quad k_2.$$

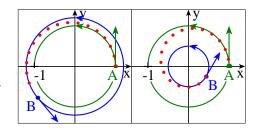

4 arguments, following the method identifier, are α, k_1, β, k_2 .

3. [/Conc2 r2 phi2]

Concentric boundary conditions: polar coordinates (r, φ) of point A are $(r_1=1, \varphi_1=0)$, those of point B are (r_2, φ_2) , given as arguments, such that $\pi < \varphi_2 \le 2\pi, r_2 \ne 1$:

$$A = (x_1, y_1) = (1, 0), \tau_1 = \frac{\pi}{2}, k_1 = 1,$$

$$B = (x_2, y_2) = \begin{pmatrix} r_2 \cos \varphi_2 \\ r_2 \sin \varphi_2 \end{pmatrix}, \tau_2 = \varphi_2 + \frac{\pi}{2}, k_2 = \frac{1}{r_2}.$$

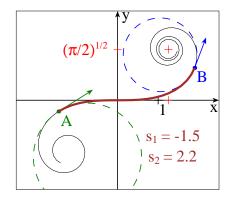

4. [/Ell2 a b]

Boundary coonditions are those of a quarter of ellipse...

5. [/Cornu2 s1 s2]

Boundary coorditions are borrowed from the Cornu spiral with $k(s) = \frac{1}{2}s$, $s_1 \le s \le s_2$:

Both the arc of the Cornu spiral and the approximating curves will be shown in the output pages.

6. [/LogSpir2 nu phi2]

Boundary conditions are borrowed from the logarithmic spiral with polar equation

$$p(\varphi) = \exp(\varphi \cot \nu), \quad 0 < \nu < 180^{\circ}, \quad \varphi \in [0; \varphi_2].$$

7. [/ABpp4 alpha beta p1 p2]

(bilens parameters; for internal use).

The entry /UserPhiData value serves to select solutions from the whole family of solutions. If absent, default /UserPhiData [0.] is assumed. Possible values are:

```
/UserPhiData N, N integer. Tries to find solutions for 2N+1 possible values of the family parameter \Phi (2N+3?). For N=3: \{-\Phi_{max}, -\Phi_2, -\Phi_1, \Phi_0 = 0., \Phi_1, \Phi_2, \Phi_{max}\}.
```

/UserPhiData [] (empty array) – as the previous one with some automatic selection of N.

```
/UserPhiData step, step is real, in degrees (e.g., 5., not 5). Tries to find solutions for \Phi \in \{0., \pm \text{step}, \pm 2 \cdot \text{step}, \pm 3 \cdot \text{step}, \dots, \pm \Phi_{max}\}.
```

```
/UserPhiData [Phi1 Phi2 Phi3 ... PhiN] (reals) — list of desired family parameters. Note that such array can be set with PostScript for-loop as /UserPhiData [Phi1 step Phi2 {} for]. E.g., /UserPhiData [ -6. 1.5 3.1 {} for] produces the array /UserPhiData [ -6. -4.5 -3. -1.5 0. 1.5 3.].
```

Other options are listed below (not yet commented):

```
/Margin real % margins in mm
/Margin int % margins in pt: /Margin 72 corresponds to 1 inch.
```

Note that A4 paper is 210 x 297 mm, or 595 x 842 pt.

```
/OutputFile string % e.g., (/home/ak/tmp/mySpiral_XY.txt)
/BaseLineSkip 20
/ShowChaque true % Show page for every solution found
/MaxLength 1000. % Reject too long curves (usually applied to curves with inflecti
```

About PostScript error messages.

```
Error messages due to PostScript syntax violation...
Errors at the attempt to output to disk, forbidden by default...
Run-time errors...
```
